

Monthly indicator over household consumption in the retail trade

Daniel Lennartsson, Statistics of Sweden

Key words: Retail trade, Household consumption, Household consumption for retail trade, Short term statistics

The project has as purpose to develop a monthly indicator of household consumption in the retail trade. Two different models has been tested. In the first model the calculation has been done at the activity level. This mean that the share that the activity sell to household has been included in the calculation of the total retail trade. The share of the turnover that is sold to household is calculated on yearlys basis in the survey Retail trade 2002. The deflation is done at activity level with an activity price index. In the second model the calculation has been done at the goods level with help from the household consumption matrix in the National accounts. The deflation has been done different goods price indicies. In the report the two different models are described in detail.
